COMPUTER SCIENCE 112 - FALL 2016
MIDTERM EXAM 2

Name:

- Be sure your test has 3 questions.

- **DO NOT TEAR OFF THE SCRATCH PAGES OR REMOVE THE STAPLE.**

- Be sure to fill your name and circle your recitation above, and your name in all subsequent pages where indicated.

- This is a CLOSED TEXT and CLOSED NOTES exam. You MAY NOT use calculators, cellphones, or any other electronic device during the exam.

Do not write below this line

Question	Max	Score
1 BST/AVL Tree	25	
2 Huffman Coding	25	
3 Hash Table	25	
TOTAL		

1. **BST/AVL Tree (25 pts;** $5 + 5 + 7 + 8$**)**

   For (a) and (b):

   Consider two binary search trees A and B. (These are NOT AVL trees, just plain binary search trees.) BST A has m nodes, and BST B has n nodes. Assume neither tree has duplicates. We wish to find the common items in A and B. For each of the following, derive the running time as asked, with reasoning. No reasoning = no credit.

   (a) We will perform an inorder traversal of A, and for each item encountered, we will perform a search in B. What is the **worst-case** big O running time of this approach?

   (b) We will perform an inorder traversal of A, appending the items to an output array as they are encountered. We will do the same for B, appending to a second output array. Assume there is enough space in each array to hold all items that are appended. We will then find the common items in these two output arrays. What is the **worst-case** big O running time?

   (c) Suppose a BST (not AVL) stores some integers in the range 1 to 500. We will perform a search for the value 225, and keep a list of the values encountered on the search path through the BST. For each of the following sequences of values, say whether or not it is a possible search path. If yes, show the actual path (with branches), if not, explain why.

      i. $500, 400, 200, 300, 230, 350, 225$

CS 112 Fall '16 Exam 2; Name: _____

ii. $500, 225, 150, 320, 200, 225$

iii. $50, 100, 300, 40, 120$

(d) Words are read from an input file, converted to lowercase, and inserted into an AVL tree one word at a time. Each node of the tree stores a word, along with a count of its occurrences in the file, and the tree is ordered alphabetically by words. If there are k <u>distinct</u> words, and n words in all in the file, what would be the worst case big O time to store all the words in the tree? Count word comparisons (each is unit time) ONLY. Show your work.

2. **Huffman Coding (25 pts,** $10 + 10 + 5$**)**

   Given the following set of character-probability pairs:

   ```
   (C, 0.1), (D, 0.1), (R, 0.2), (S, 0.3), (E, 0.3)
   ```

   (a) Build a Huffman tree for this character set. Fill in the following table to show the queue L, which will start with the leaf nodes for the symbols, and the queue T, which will contain the subtrees as they are built. Draw the tree shape for each subtree in T. Each row of the table must show the contents of the queues at the end of that step. (Start by filling in the queue L contents in the first line.) The last step should have a single tree (final Huffman tree) in the queue T. (Ties in probability values are broken arbitrarily, and it doesn't matter which dequeued node goes left and which goes right when building a subtree.)

   ```
   Step                Queue L                 Queue T
   ------------------------------------------------------------------
   1                                           Empty
   ```

CS 112 Fall '16 Exam 2; Name: _____

(b) Assume that enqueue, dequeue, creating a leaf node, creating a new tree out of two subtrees, and picking the minimum of two probabilities all take unit time. Ignore the time for all other operations. How many total units of time (exact number, not big O) did it take to build your tree in part (a)? Show your work.

(c) (This part is not related to the specific example of parts (a) and (b).)

Suppose a character string of length n is encoded to k bits using Huffman coding. Consider decoding this back to the original character string. Briefly describe the decoding process. How many units of time (NOT big O) would the decoding take? Derive your answer, starting with specifying what unit time operation(s) you are counting.

3. **Hash Table (25 pts;** $7 + 10 + 8$**)**

   You are given the following classes:

```java
class LLNode {
    String key;                          class HashTable {
    String value;                            LLNode[] table;
    int hashCode;                            int numValues;
    LLNode next;                             float loadFactorThreshold;
    LLNode(String key, String val,          HashTable(LLNode[] table, int numVal,
    int hashCode, LLNode next) {            float lfT) {
        this.key = key;                         this.table = table;
        this.value = value;                     this.numValues = numVal;
        this.hashCode = hashCode;               this.loadFactorThreshold = lfT;
        this.next = next;                   }
    }                                    }
}
```

(a) Implement a method in the Hashtable class to-insert a key-value pair into the hash table, using the function h **mod** N to map a hash code h to a table location. N is table size (capacity):

```java
/**
 * Inserts (key, value) into hash table,
 * calls rehash method (part b) if load factor threshold is exceeded.
 * Note: String class implements the hashCode method.
 * @param key Key to insert
 * @param value Value to insert
 */
public void insert(String key, String value) {
```

(b) Also implement a `rehash` method, which doubles the table size when expanding it. Your implementation <u>MUST NOT</u> end up creating any new nodes - it should ONLY recycle the nodes already in the table

```
public void rehash() {
```

(c) Suppose you insert 125 integer keys into a hash table with an initial capacity of 25 and a load factor threshold of 2. The hash code is the key itself, and the function key **mod** `table_capacity` is used to map a key to a table position. Derive the total units of time that will be used to insert all keys, ONLY counting one unit of time each to do the mapping, insert an entry into a linked list, and check load factor against threshold. Assume a rehash doubles the table capacity, and the load factor is checked AFTER an entry is mapped and inserted into a chain. Show work.
